AN INTEGRAL COMPONENT OF THE TREATMENT OF PAIN AND INFLAMMATION IN THE ORAL CAVITY IN 60 COUNTRIES WORLDWIDE!

- JAWS FRACTURES
- IMPLANTS PLACEMENT
- WOUNDS OF ORAL CAVITY

LOCAL ANESTHETIC AND ANTI-INFLAMMATORY EFFECT

SUMMARY OF PRODUCT CHARACTERISTICS

NAME OF THE MEDICINAL PRODUCT: Tantum Verde 0.15% mouthwash, QUALITATIVE AND QUANTITATIVE COMPOSITION. Each 100 ml contains: active ingredient: benzylamine hydrochloride 0.15 g (equivalent to 0.134 g of benzylamine). Therapeutic indications: Treatment of symptoms such as irritation/inflammation including those associated with pain in the oropharyngeal cavity (e.g., gingival, stomatological and pharyngitis), including those resulting from conservative or extracting dental therapy. Dosage and method of administration: Pour 15 ml of Tantum Verde mouthwash into the measuring cap. 2-3 times per day, using 60 ml of concentration or diluted, if needed, add 15 ml of water to the graduated cup. Do not exceed the recommended dosage. Contraindications: Hypersensitivity to benzylamine or to any of the excipients. PHARMACOLOGICAL PROPERTIES. Pharmacodynamic properties. Pharmaherapeutic group: Pharmacological drugs: other agents for local oral treatment, ATC code: M01AD01. Clinical studies demonstrate that benzylamine is effective in relieving pain from localized lesions of the mouth and pharynx. In addition, benzylamine possesses a moderate local anesthetic effect. Pharmacokinetic properties. Absorption. Absorption through the oropharyngeal mucosa is demonstrated by the presence of measurable concentrations of benzylamine in human plasma. These levels are insufficient to produce systemic effects. Distribution. When applied locally, benzylamine has been shown to accumulate in inflamed tissues where it reaches effective concentrations because of its capacity to penetrate the epithelial lining.

Information about medicines. Information for health care professionals for use in professional activities.

About the Journal: Aims and Scope

Official Title
Journal of Diagnostics and Treatment of Oral and Maxillofacial Pathology

Standard Abbreviation: ISO 4

Acronym
JDTOMP

International Standard Serial Number (ISSN)
Electronic ISSN 2522-1965

Aims & Scope
This is a monthly peer-reviewed oral and maxillofacial surgery journal focused on: microvascular and jaw reconstructive surgery, dental implants, salivary gland tumors/diseases, TMJ lesions, virtual surgical planning, implementation of ultrasonography into the practice of oral and maxillofacial surgeons.

Editorial Board (EB) Composition
• EB shows significant geographic diversity representing 30 opinion leaders from 13 countries: Brazil, Canada, Colombia, Greece, Hong Kong (SAR, China), India, Israel, Italy, Slovak Republic, Spain, Ukraine, United Arab Emirates, and United States.
• The majority of the EB Members have a discernible publication history in Scopus, Web of Science, and journals with a high impact factor.
• The publication records of all EB members are consistent with the stated scope and published content of the journal.
• The journal has a several full-time professional editors.
• Gender distribution of the editors: 10% women, 90% men, 0% non-binary/other, and 0% prefer not to disclose.

Frequency
12 issues a year (from January 2020)

Publication History
2017: 4 issues a year
2018: 4 issues a year
2019: 10 issues a year
From 2020: 12 issues a year

Publishing Model
Journal of Diagnostics and Treatment of Oral and Maxillofacial Pathology is a fully online-only open access and peer-reviewed publication.

Type of Peer Review
The journal employs “double blind” reviewing.

Article Publishing Charge (APC)
The APC in this journal is 100 USD and 50 USD (excluding taxes) depending on the article’s type. Details at website: dtjournal.org.

13 Types of Articles Currently Published by the Journal
Editorials/Guest Editorials/Post Scriptum Editorials, Images, Case Reports/Case Series, Original Articles, Review Articles, Discussions, Paper Scans (synonyms: Review of Articles, Literature Scan), Book Scans (synonym: Book Reviews), Letters to the Editor (synonym: Letters), and Viewpoints.

State Registration: Ministry of Justice of Ukraine

© 2022 OMF PUBLISHING, LLC
**Composition:**

*active substance*: benzydamine hydrochloride;

100 mL of solution contain benzydamine hydrochloride 0.15 g;

*excipients*: ethanol 96%, glycerol, methyl parahydroxybenzoate (E 218), flavor (menthol), saccharin, sodium hydrocarbonate, Polysorbate 20, Quinoline Yellow (E 104), Patent Blue V (E 131), purified water.

**Dosage form.** Oromucosal solution.

**Basic physical and chemical properties:** a clear green liquid with a typical mint flavor.

**Pharmacotherapeutic group.** Dental preparations. Other agents for local oral treatment.

ATC code: A01A D02.

**Pharmacological properties.**

*Pharmacodynamics.*

Benzydamine is a non-steroidal anti-inflammatory drug (NSAID) with analgesic and antiexudative properties.

Clinical studies have shown that benzydamine is effective in the relief of symptoms accompanying localized irritation conditions of the oral cavity and pharynx. Moreover, benzydamine has anti-inflammatory and local analgesic properties, and also exerts a local anesthetic effect on the oral mucosa.

*Pharmacokinetics.*

Absorption through the oral and pharyngeal mucosa has been proven by the presence of measurable quantities of benzydamine in human plasma. However, they are insufficient to produce any systemic pharmacological effect. The excretion occurs mainly in urine, mostly as inactive metabolites or conjugated compounds.

When applied locally, benzydamine has been shown to cumulate in inflamed tissues in an effective concentration due to its ability to permeate through the mucous membrane.

**Clinical particulars.**

*Indications.*

Symptomatic treatment of oropharyngeal irritation and inflammation; to relieve pain caused by gingivitis, stomatitis, pharyngitis; in dentistry after tooth extraction or as a preventive measure.

*Contraindications.*

Hypersensitivity to the active substance or to any other ingredients of the product.

*Interaction with other medicinal products and other types of interaction.*

No drug interaction studies have been performed.

*Warnings and precautions.*

If sensitivity develops with long-term use, the treatment should be discontinued and a doctor should be consulted to get appropriate treatment.

In some patients, buccal/pharyngeal ulceration may be caused by severe pathological processes. Therefore, the patients, whose symptoms worsen or do not improve within 3 days or who appear feverish or develop other symptoms, should seek advice of a physician or a dentist, as appropriate.

Benzydamine is not recommended for use in patients hypersensitive to acetylsalicylic acid or other non-steroidal anti-inflammatory drugs (NSAIDs).

The product can trigger bronchospasm in patients suffering from or with a history of asthma. Such patients should be warned of this.

For athletes: the use of medicinal products containing ethyl alcohol might result in positive antidoping tests considering the limits established by some sports federations.
Use during pregnancy or breast-feeding
No adequate data are currently available on the use of benzylamine in pregnant and breastfeeding women. Excretion of the product into breast milk has not been studied. The findings of animal studies are insufficient to make any conclusions about the effects of this product during pregnancy and lactation.

The potential risk for humans is unknown.
TANTUM VERDE should not be used during pregnancy or breast-feeding.

Effects on reaction time when driving or using machines
When used in recommended doses, the product does not produce any effect on the ability to drive and operate machinery.

Method of administration and doses.
Pour 15 mL of TANTUM VERDE solution from the bottle into the measuring cup and gargle with undiluted or diluted product (15 mL of the measured solution can be diluted with 15 mL of water). Gargle 2 or 3 times daily. Do not exceed the recommended dose.

Children.
The product should not be used in children under 12 years due to a possibility of ingestion of the solution when gargling.

Overdosage.
No overdose has been reported with benzylamine when used locally. However, it is known that benzylamine, when ingested in high doses (hundreds times higher than those possible with this dosage form), especially in children, can cause agitation, convulsions, tremor, nausea, increased sweating, ataxia, and vomiting. Such acute overdose requires immediate gastric lavage, treatment of fluid/salt imbalance, symptomatic treatment, and adequate hydration.

Adverse reactions.
Within each frequency group, the undesirable effects are presented in order of their decreasing seriousness.

Adverse reactions are classified according to their frequency: very common (≥ 1/10); common (1/100 to <1/10); uncommon (1/1,000 to <1/100); rare (1/10,000 to <1/1,000); very rare (<1/10,000); frequency unknown (cannot be estimated from the available data).

Gastrointestinal disorders: rare – burning mouth, dry mouth; unknown – oral hypesthesia, nausea, vomiting, tongue edema and discoloration, dysgeusia.

Immune system disorders: rare – hypersensitivity reaction, unknown - anaphylactic reaction.

Respiratory, thoracic and mediastinal disorders: very rare –laryngospasm; unknown – bronchospasm.

Skin and subcutaneous tissue disorders: uncommon – photosensitivity; very rare – angioedema; unknown – rash, pruritus, urticaria.

Nervous system disorders: unknown – dizziness, headache.

TANTUM VERDE contains methyl parahydroxybenzoate, which can cause allergic reactions (including delayed-type reactions).

Shelf life. 4 years.

Storage conditions.
Do not store above 25°C. Keep out of reach of children.

Packaging.
120 mL of solution in a bottle with a measuring cup; 1 bottle per cardboard box.

Dispensing category.
Over-the-counter medicinal product.

Manufacturer.

Location of the manufacturer and its business address.
Via Vecchia del Pinocchio, 22 – 60100 Ancona (AN), Italy.

Date of the last revision of the text.
September 26, 2018.

Ultrasonographic Identification of the Parotid Cystadenolymphoma (Warthin’s Tumor) by Oral and Maxillofacial Surgeons: Supplement to the Matsuda and Colleagues’ Classification

Olha S. Cherniak¹,*, Lilia A. Savchuk², Oksana V. Ripolovska³, Valentina H. Demidov⁴, Oleksandr A. Nozhenko⁵, Valentyna I. Zaritska⁶, & Pavlo P. Snisarevskyi⁷

SUMMARY

Warthin’s tumor (WT), which is also known as papillary cystadenoma lymphomatosum, monomorphic parotid adenoma, adenolymphoma, cystadenolymphoma, and branchiogenic adenoma, is to be differentiated (in surgical practice) from other parotid masses. The purposes of our retrospective case series study are: (1) to describe ultrasound morphology (sonomorphology) of the WT in patients referred to our hospital, (2) based on the presented cases to propose a supplement to the Matsuda and colleagues’ classification (2017) of anechoic area patterns of the WT, and (3) to expand the knowledge of oral and maxillofacial surgeons for the preoperative ultrasonographic verification of the WT and for choosing the most appropriate surgical technique. Over three years, 5 patients (mean age, 65.4 years) with parotid WT had been examined with gray-scale, color, and power Doppler ultrasonography. Cystic components are visualized in all five WT cases but in different proportions. Case 1 and 4 showed the presence of septations. According to Matsuda and colleagues’ (2017)
classification of anechoic area patterns, in our cases the US patterns of the WTs belong only to Group 3 (i.e., with large anechoic areas) \( (n = 4) \) and Group 4 (multiple and sponge-like anechoic areas) \( (n = 1) \). Moreover, based on the presented five cases, we offer an addition to the classification of Japanese authors. In conclusion, our supplement to Matsuda and colleagues’ classification of anechoic area patterns of the WT can help surgeons around the globe to be more accurate in preoperative verification of cystadenolymphoma. This case series illustrate the growing importance of ultrasonography in the professional life of oral and maxillofacial and head and neck surgeons. Based on the cystic structure of this benign tumor and the ultrasound appearance presented in our case series, we propose to continue using the term “cystadenolymphoma” with a purpose to emphasize the tumor’s structure.

INTRODUCTION

In 1929, Aldred Scott Warthin was the next one, after Hilderand (1895), and Albrecht and Arzt (1910), who described two similar lower pole–located parotid tumors and named such neoplasm as papillary cystadenoma lymphomatosum.\(^1\)\(^{-4}\) There are other names appeared from 1929 which describe this pathological entity.\(^5\) Among them monomorphic parotid adenoma,\(^6\) adenolymphoma, cystadenolymphoma,\(^7\)\(^{-9}\) branchiogenic adenoma,\(^10\) and Warthin’s tumor (WT).\(^11\)\(^{-14}\) The chronology of WT naming is perfectly depicted in the Jerry Chapnik’s study (1983).\(^1\) WT is a second (29.2 percent) most popular parotid benign tumor after the pleomorphic adenoma (65.6 percent) (Pinkston and Cole, 1999).\(^15\) Despite WT is predominantly founded in parotid glands, some authors report cases of nasopharyngeal adenolymphoma\(^16\), laryngeal adenolymphoma\(^17\)\(^{-19}\) or even arising from minor salivary glands\(^20\).

Literature revealed that WTs can have parotid and extraparotid location.\(^10\) Snyderman et al (1986) also noted that adenolymphomas can arise from the periparotid lymph nodes.\(^21\) According to Hellquist and Skalova (2014), parotid WT is usually noted in the caudal pole of the parotid gland—the part of the gland that has the most intraparotid lymph nodes.\(^10\)

Unfortunately, malignization of WT is possible. That was proved by Yamada et al (2002) and Yu et al (2016) who described the cases of mucoepidermoid carcinoma arising in Warthin’s tumor.\(^17\)\(^{-18}\)

Choosing the best imaging for establishing the correct preoperative diagnosis is crucial. Kim et al (2004) emphasized that such preoperative imaging as ultrasonography (US) can help reaching two goals in parotid region—(1) determination of the probable histologic diagnosis of the parotid mass and (2) determination of the extent of the operation.\(^19\)

Usually, the differential diagnosis in case of parotid mass with no facial nerve dysfunction should be made between mixed (i.e., pleomorphic adenoma) and WT. Many studies describe the US appearance of the WT.\(^19\)\(^{-25}\) But, the work of Matsuda and colleagues’ (2017) is especially worth of attention due to the novel US classification which can be helpful both to sonographers and to oral and maxillofacial surgeons.\(^25\)

The purposes of our retrospective case series study are: (1) to describe ultrasound morphology (sonomorphology) of the WT in patients referred to our hospital, (2) based on the presented cases to propose a supplement to the Matsuda and colleagues’ classification (2017) of anechoic area patterns of the WT,\(^25\) and (3) to expand the knowledge of oral and maxillofacial surgeons for the preoperative ultrasonographic verification of the WT and for choosing the most appropriate surgical technique.

MATERIALS AND METHODS

We retrospectively reviewed the clinical, ultrasonographic, intraoperative, macroscopic, and histopathologic data of patients with parotid adenolymphoma (i.e., WT) at Kyiv Regional Clinical Hospital between December 2014 and June 2016. US and its interpretation have been done by three experienced doctors of ultrasound diagnostics (O.S.C., her experience is 16 years; O.V.R., her experience is 29 years; L.A.S., her experience is 31 years). US was performed on two ultrasound machines (HD11XE, the Philips, Amsterdam, the Netherlands) using linear array probe (also known as linear transducer) (the Philips L12-3 [12-3 MHz], Philips, Amsterdam, the Netherlands) and curved array probes (also known as convex transducer) (Philips C5-2 [5-2 MHz], Amsterdam, the Netherlands). The sample included five patients (3 male and 2 female patients) with a mean age of 65.4 years (range, 49 to 78 years). Patients underwent parotid tumors removal applying extracapsular dissection with facial nerve
dissection (Gleave, 1995; Witt and Rassekh, 2018) and partial parotidectomy.26,27 All five patients signed an informed consent agreement. We evaluated 5 tumors that were histopathologically diagnosed as Warthin's tumor between December 2014 and June 2016. Histological diagnosis of adenolymphoma in all five cases was verified by two experienced pathologists (V.I.Z., her experience is 23 years; P.P.S., his experience is 18 years). Gray-scale ultrasound images (also known as ‘B-mode ultrasound images’) were used for the tumors’ long-to-short diameter measurements.

For the assessment of ultrasound patterns of WTs we used Matsuda and colleagues’ (2017) classification of anechoic area patterns and their criteria for reassessment of ultrasonographic features of the parotid tumors.25 We obtained approval for this retrospective review of patients’ data from the Kyiv Regional Clinical Hospital review board.

RESULTS

Results of our case series study are presented in Tables 1 and 2. Male to female ratio in our retrospective case study was 3:2. The average age of the managed patients was 65.4 years. Cystic components are visualized in all five WT cases but in different proportions. Case 1 and 4 showed the presence of septations. According to Matsuda and colleagues’ (2017) classification of anechoic area patterns,25 in our cases the US patterns of the WTs belong only to Group 3 (i.e., with large anechoic areas) (n = 4) and Group 4 (multiple and sponge-like anechoic areas) (n = 1). Moreover, based on the presented five cases, we offer an addition to the classification of Japanese authors. The Group 3 can be divided into Group A and B depending on the cystic chambers volume. Group 3A will include Warthin’s tumors that show “~half anechoic-half echoic” ultrasound appearance (i.e., ~half cystic-half solid structure) (what is confirmed by Case 1, 3, and 5 in our study) and the Group 3B will include large anechoic areas with echoic hair-like strands (i.e., macrocystic ultrasound appearance with thin septations) (confirmed by Case 4). Edge artifact and posterior acoustic enhancement artifact were two common US artifacts noted on the examined sonograms. A mean long-to-short diameter of WTs was 3.14 × 2.01 cm (range of long diameter, 2.31 to 4.0 cm; range of short diameter, 1.37 to 3.1 cm).

CASE SERIES

~HALF CYSTIC-HALF SOLID: MATSUDA ET AL GROUP 3A (CASE 1)

A 49-year-old male was referred to the Kyiv Regional Clinical Hospital in December 2014 with a facial asymmetry in the left parotid region (Fig 1). A palpable painless movable lesion in the projection of left parotid gland was noted. Patient reported slow growth of the lesion during last years. Gray-scale US revealed parotid mass of the left parotid gland with multicystic structure and septations (Fig 2). The long-to-short tumor diameter reached 3.3 × 3.1 cm. US appearance of the mass corresponds to the Group 3 of Matsuda et al classification (2017) of anechoic area patterns and Grade 1 vascularization (two flow signals were noted). The surgery (tumor removal with extracapsular dissection and facial nerve dissection) was done by V.H.D. under general anesthesia and the diagnosis of adenolymphoma was established by pathologists (V.I.Z. and P.P.S.).

MULTIPLE AND SPONGE-LIKE ANECHOIC AREAS: MATSUDA ET AL GROUP 4 (CASE 2)

A 65-year-old Caucasian female was referred to the Kyiv Regional Clinical Hospital in June 2015 due to the facial asymmetry in the region of left parotid gland. US (Fig 3) showed an intraparotid localization of oval tumor with well-defined borders, mixed hypoechoic structure which measured 4.0 × 2.12 cm. US appearance of the mass corresponds to the Group 4 (multiple and sponge-like anechoic areas) of Matsuda et al classification (2017) of anechoic area patterns and Grade 2 vascularization (several linear flow signals). Tumor removal (including extracapsular dissection and facial nerve dissection) was done by V.H.D. under general anesthesia and the diagnosis of adenolymphoma was established by pathologists (V.I.Z. and P.P.S.).

MACROCYSTIC WITH SEPTATIONS: MATSUDA ET AL GROUP 3B (CASE 4)

A 78-year-old Caucasian male was referred to our Department in June 2016 with soft tissue asymmetry in the left upper neck region (Fig 5). Gray-scale US showed presence of well-defined heterogenic parotid mass (Fig 6) which is visualized as multilocular cystic tumor (multiple anechoic areas with echogenic hair-like strands) due to the insignificant part of solid components. The long-to-short diameter of this tumor measured 3.44 × 1.62 cm. The tumor was elongated and rounded in shape at the edge of the mandible. Such US appearance was typical to Group 3 of Matsuda et al classification (2017) of anechoic area patterns and Grade 1 vascularization (flow signals were not noted). Tumor removal (with extracapsular dissection and facial nerve dissection) was done by V.H.D. under the general anesthesia. Cystic fluid was visualized after careful incision of one side of the Warthin’s tumor specimen (Fig 7A). Figure 7B demonstrates the part of aspirated fluid inside the 10.0-ml syringe. Histological diagnosis of adenolymphoma was established by pathologists (P.P.S. and V.I.Z.).
FIGURE 1. Case 1. Preoperative view of a 49-year-old male patient with facial asymmetry (arrow) in the left parotid region. Printed with permission and copyrights retained by V.H.D.

FIGURE 2. Case 1. A 49-year-old male patient. Conjoined gray-scale sonograms of WT of the left parotid gland. Notes tumor's multicystic structure with septations (arrowhead). Tumor's borders are well defined, echogenicity is mixed hypoechoic. PG, parotid gland; CP, cystic part of the tumor; SP, solid part of the tumor; M, mandible; MM, masseter muscle; SCMM, sternocleidomastoid muscle. Asterisk labels posterior acoustic shadowing deeper to the superficial surface of mandible. The depth of sonograms is 4.0 cm. Letter “P” inside the blue circle at the upper left corners of the sonograms indicates on the probe's side (corresponds to the probe bump on the left side). Printed with permission and copyrights retained by O.S.C.
FIGURE 3. Case 2. Preoperative gray-scale (A) and color Doppler (C) sonograms in a 65-year-old female with a WT of the left parotid gland. Sonograms show an oval tumor with well-defined borders, mixed hypoechoic structure which measured 4.0 × 2.12 cm. Two × calipers at the image A measure the tumor’s transverse size (2.12 cm). Notes multiple and sponge-like anechoic areas. CP, cystic part (anechoic area) of the mass; SP, solid part mass. The artifact of acoustic enhancement is labeled by asterisk. Color Doppler US revealed vascularization of the tumor (arrowhead). Images B and D show positions of the linear transducer. The depth of these cropped sonograms is 3.0 cm. Printed with permission and copyrights retained by O.S.C.
FIGURE 4. Case 3. A 68-year-old male patient. Preoperative gray-scale transversal (A) and longitudinal (C) sonograms of WT in the left parotid gland (PG). CP, cystic part of WT; SP, solid part of the WT. Asterisk labels the artifact of acoustic enhancement and two circles indicate the edge artifact. Images B and D show positions of the linear probe. The depth of these cropped sonograms is 3.0 cm. Calipers '+' and '×' measure the long-to-short WT diameter (A) which reaches 1.88 × 1.28 cm. The tumor lies at a depth of 1.67 cm (distance between medial border of the tumor and skin surface). Longitudinal size of the WT (distance between calipers '×' and '+' ) reach 2.31 × 1.37 cm. The tumor lies at a depth of 1.65 cm (distance between medial border of the tumor and skin surface). Artifact of the posterior acoustic enhancement is stronger in those posterior areas that were located behind the areas of the tumor with a greater number or size of cystic cavities. The edge artifact (visualized as acoustic shadowing artifact) is labeled by two circles. Printed with permission and copyrights retained by O.V.R.
FIGURE 5. Case 4. Preoperative view of the 78-year-old male patient with soft tissue asymmetry (arrow) in the left upper neck region. Printed with permission and copyrights retained by V.H.D.
FIGURE 6. Case 4. A 78-year-old male patient. Preoperative longitudinal gray-scale sonograms (A, C) of the WT in the left parotid gland (PG). Tumor shows macrocystic appearance (CP, cystic part) with septations (arrowhead). Asterisk labels acoustic shadowing behind the superficial surface of the mandible (M). The long-to-short diameter (A) of this tumor measured 3.44 × 1.62 cm (calipers '+' and '×'). The depth of these cropped sonograms is 3.0 cm. B and D, position of the linear probe upon the US. Printed with permission and copyrights retained by O.S.C.
FIGURE 7. Case 4. Cystic fluid (asterisk) is visualized after careful incision of one side of the Warthin's tumor specimen (A). B, part of aspirated fluid inside the 10.0-ml syringe. Printed with permission and copyrights retained by V.H.D.

~HALF CYSTIC-HALF SOLID: MATSUDA ET AL GROUP 3A (CASE 5)

A 67-year-old Caucasian female was referred to our surgical department in June 2016 complaining for the existing painless mass in the right upper neck region (Fig 8). According to preoperative US (Fig 9), the long-to-short diameter of the tumor at B-mode was 2.69 × 1.84 cm. US appearance corresponds to Group 3 of Matsuda et al classification (2017) and Grade 2 vascularization (with three punctiform flow signals). Video (Supplemental Video Content) demonstrates longitudinal gray-scale ultrasonography of the Warthin's tumor of the right parotid gland. Video is available in the page of the full-text article on www.dtjournal.org and in the YouTube channel, available at https://www.youtube.com/shorts/jKGX-t9rvv8. Total video's duration: 22 sec. Tumor was removed by O.A.N. under the general anesthesia applying partial parotidectomy. Histologically, the diagnosis of adenolymphoma was established (P.P.S. and V.I.Z.).

DISCUSSION

Matsuda et al (2017) perfectly described four reasons why ultrasonography (US) is advantageous over other imaging technologies (computed tomography [CT], magnetic resonance imaging [MRI]) in case of parotid tumors. The reasons are: (1) simplicity, (2) low cost, (3) non-invasiveness, and (4) real-time images (sonograms). Moreover, similar to otolaryngology (Hoffman and Pagedar, 2018; Slough et al, 2019), US is increasingly becoming an integral part of an oral and maxillofacial surgery practice.

To our knowledge and due to the English literature search, Neiman et al (1976) were the first ones who published the sonographic image of the WT. Gretchen A. W. Gooding (1980) presented the sonogram of his patient with the WT. Of course, the quality of the ultrasound images evolved significantly from the late 1970s, and in 2022, we can absorb all the advantages of the highly developed US machines. High resolution gray-scale sonograms, cine-loops, sonopalpation, color, and power Doppler is not a full list of options, radiologist and surgeons can used in their practice. Even the method of sonograms storage evolved from using a Polaroid® camera (Ishikawa et al, 1983) to digital archiving in every US machine and possibility to transfer and reproduce it at electronic devices (laptops, smartphones, and tablets). Sonograms of the WTs presented in the works from late 1970s and early 1980s

**FIGURE 9.** Case 5. Preoperative US in a 67-year-old female patient. The long-to-short diameter of the TW at this B-mode sonogram (A) measured 2.69 × 1.84 cm (calipers “+” and “×”). PG, parotid gland; SP, solid part of the WT; CP, cystic part of the WT; M, mandible. The depth of this cropped sonogram is 3.0 cm. B, position of the linear probe upon B-mode US. Printed with permission and copyrights retained by O.S.C.
VIDEO. Case 5. A 67-year-old female patient. Supplemental Video Content demonstrates longitudinal gray-scale ultrasonography of the Warthin’s tumor of the right parotid gland. Imaging clearly shows half anechoic-half echoic ultrasound appearance (i.e., half cystic-half solid structure) (Matsuda and colleagues’ Group 3, Subgroup A). PG, parotid gland; SP, solid part of the WT; CP, cystic part of the WT. The depth of gray-scale ultrasonography is 4.0 cm. Video is available in the page of the full-text article on www.dtjournal.org and in the YouTube channel, available at https://www.youtube.com/shorts/jKGX-t9rw8.

Total video’s duration: 22 seconds. The video is a three-second recording of gray-scale ultrasound that is repeated several times for better visualization.

Printed with permission and copyrights retained by O.S.C.
clearly indicate us how far the evolution of the US had come from that moment.\textsuperscript{35–37,4} It is interesting that for almost all 46 years (since 1976 and Neiman’s work), the constant tasks of radiologists and surgeons were attempts to describe the characteristic ultrasound pictures for parotid adenolymphoma.

Sriskandan and colleagues (2010) published the useful criteria for the assessment of ultrasonographic features of parotid and lymph node lesions.\textsuperscript{38} Knopf et al (2012) are also presented multimodal diagnostic pathway for unification of different ultrasonographic techniques for identification parotid WT, mixed tumor, and even carcinomas.\textsuperscript{22}

In an own sonographic study, Miao et al (2015) divided pleomorphic adenomas and WTs into three groups: (1) without macroscopic cystic structures, (2) with <50 percent macroscopic cystic structures; and (3) with ≥50 percent macroscopic cystic structures.\textsuperscript{24} Matsuda and colleagues’ classification (2017) of the benign parotid tumors which is based on anechoic area patterns is more than worth of attention of oral and maxillofacial surgeons.\textsuperscript{25} The surgeons should understand the basic US terms. For example, anechoic area is black color area on the screen of the US machine or sonogram (Ihnatsenka and Boezaart, 2010),\textsuperscript{39} and is common for the fluid-filled areas of the tissues. Hyperechoic area—the white area on sonogram—is typical for bone structures (e.g., surface of the mandible).\textsuperscript{39} Dark gray areas—i.e., hypoechoic areas—are typical for adipose tissue, lymph nodes, cartilages, tumors, etc.\textsuperscript{39}

In some cases, the ultrasound appearance of WT can mimic pleomorphic adenoma.\textsuperscript{38} For example, cystic WTs can be confused with simple cysts (Koenig et al, 2017).\textsuperscript{40} Sommmer et al (1979) and Wu et al (2020) perfectly described ultrasound artifacts—from physics to clinics.\textsuperscript{41,42} Typical US artifacts visualized on the sonograms upon the WTs’ diagnostics in the parotid area in our patients were acoustic shadowing (behind the bony structures [mandible]), the edge artifact, and acoustic enhancement.

Ahuja et al (2007) showed three typical US appearances of the WT: (1) with cystic component, solid papillary portion, and thin septa (i.e., Matsuda Group 3A) (is similar to our case 5), (2) with multiple sponge-like anechoic areas (i.e., Matsuda Group 4) (is similar to our case 2), and (3) with large anechoic area (i.e., Matsuda Group 3).\textsuperscript{43}

Totally cystic WTs can be note occasionally (Rhys, 2011),\textsuperscript{44} what is similar to our case 4 in which the WT mimicked a multicameral variant of the second branchial cleft cyst due to the similar location and ultrasound appearance (Tymofieiev et al, 2017)\textsuperscript{41}

Ultrasonographic appearance of case 5 is similar to the case of a 70-year-old male patient with a WT in the right parotid gland from the study of Rong and colleagues (2014).\textsuperscript{45} WT visualized as oval-shaped mass with large anechoic areas (Matsuda Group 3).\textsuperscript{45} The literature report that typical/classic US appearance of intraparotid WT (Kamble et al, 2013)\textsuperscript{23} is a WT with the “~half cystic-half solid” structure.

Torske emphasized that cysts of the WT may contain yellow-brown fluid. This statement proved by case 4 (Figure 7A and B).\textsuperscript{46} Mantsopoulos et al (2018)\textsuperscript{6} presented B-mode sonograms of the WTs with multifocal growth (in a single organ) what is different from multicentric growth (in more than one organ) (de Werra and colleagues, 2009).\textsuperscript{47} The case of Shugar et al (1982) clearly showed evidence of three distinct WTs in every parotid gland (i.e., multicentric WT).\textsuperscript{48} The surgeons should be aware of possible synchronous unilateral parotid pleomorphic adenoma and WT as such case was presented by Heine et al (2018).\textsuperscript{49} Nascimento et al (2014) emphasized that WT can occur unilaterally or bilaterally, metachronously or synchronously.\textsuperscript{50} WT is multifocal in 20 percent. In rare cases, even the ulcerative WT can be observed.\textsuperscript{51}
The male to female ration in our study (3:2) adheres to the internationally proved data in which it ranges from 2.6:1 to 10:1 (Chapnik, 1983; Teymoortash et al, 2006). The average age of the investigated patients was 65.4 years what is similar to the reported data of Torske who reported that 6th to 7th decades are the decades of WT manifestations.

Figure 10 showed our supplement to the classification of Matsuda et al (2017).
All diagnostic measures for parotid tumor processes are subject to one goal—to choose the most appropriate type of operation. Heller and Attie (1988) and Batori et al (2002) advocated for enucleation as a recommended surgery for adenolymphoma. 52, 53 Carlson and Ord (2008) emphasized on a need to perform partial parotidectomy as WTs have a tendency to occur in the caudal part of parotid. 54 Tymofieiev (2012) emphasized, that it is impossible to determine accurately a parotid tumor type in advance when removing a tumor. 8 It is advisable at least to perform a partial parotidectomy, or better, a subtotal parotidectomy with preservation of the facial nerve branches (Tymofieiev, 2012). 8 Surgical possibilities (enucleation, parotidectomy) related with WT cases are also well described in the Iowa Head and Neck Protocols. 55, 56

Histologic subclassification of WTs was reported by Seifert et al (1980) based on their 275 WT cases. 57 This subclassification includes typical WT (77 percent), stroma-poor WT (13.5 percent), stroma-rich WT (2 percent), and metaplastic WT (7.5 percent). 57

Despite the fact that the terms adenolymphoma and Warthin's tumor are predominantly applied for the description of this pathological parotid entity, we adhere to the term “cystadenolymphoma.” Based on the macroscopic structure of this tumor, the ultrasound appearance, and opinions of experts (Teymoortash et al, 2006; Mantsopoulos et al, 2018) we recommend to use cystadenolymphoma term.

We agree with Khatib et al (2022), who noticed that case series study is weaker comparing to clinical study with a big number of patients. 58 But we hope that this article can be useful for other researchers in this topic and be a cornerstone for studies with bigger number of WT cases.

CONCLUSIONS

In conclusion, our supplement to Matsuda and colleagues’ classification 25 of anechoic area patterns of the Warthin’s tumor can help surgeons around the globe to be more accurate in preoperative verification of cystadenolymphoma. This case series illustrate the growing importance of ultrasonography in the professional life of oral and maxillofacial and head and neck surgeons. Based on the cystic structure of this benign tumor and the ultrasound appearance presented in our case series, we propose to continue to use the term “cystadenolymphoma” with a purpose to emphasize the tumor’s structure.

TERM OF CONSENT

Writing patients’ consents were obtained for publication the photos.

AUTHOR CONTRIBUTIONS

Conceptualization: Cherniak OS. Ultrasonographic data acquisition: Cherniak OS, Savchuk LA, Ripolovska OV. Surgical images acquisition: Demidov VH, Nozhenko OA. Histological data acquisition: Snisarevskyi PP, Zaritska VI. Data analysis or interpretation: Cherniak OS, Zaritska VI. Drafting of the manuscript: Cherniak OS. Critical revision of the manuscript: Cherniak OS, Zaritska VI, Nozhenko OA. Approval of the final version of the manuscript: all authors.

CONFLICT OF INTERESTS

The authors declare no conflict of interest.

FUNDINGS

No funding was received for this study.

ACKNOWLEDGMENTS

We would like to thank Ievgen I. Fesenko, DSS, PhD from Kyiv (Ukraine) for the kind support in preparing the manuscript.
